KEYS AND GROUPS

In Spark

Big Data H/M 2022 Richard McCreadie

MOTIVATION

- So far we have discussed the application of key-less transformation functions
 - i.e. functions that work on fixed number of data items, rather than variable size groups of items that share a key
- However, as demonstrated by Google's earlier Map-Reduce proposal, there are many use-cases where you might want to have a single transformer call process a number of data items grouped by a meaningful key
 - Analyse videogames by platform
 - Group students by GPA
 - Analyse webpages by host
 - ...and many many more
- Key-based grouping also has efficiency advantages, since all operations for a single key can be co-located on a single executer, reducing the need for data transfer

GROUPING DATA BY KEY

- As we have seen, when we load data in spark we get a Dataset<Row>,
 which is key-less, and we have seen previously how to use map functions to
 convert these datasets into other types
- To handle keys, Spark implements a more specialist Dataset type:
 - KeyValueGroupedDataset<KeyType,ValueType>
- As its name suggests, this is simply a Dataset that has been logically grouped by a set of user specified grouping keys

FROM A DATASET TO KEYVALUEGROUPEDDATASET

- So how do we transition from a Dataset<V> to KeyValueGroupedDataset<K,V>?
 - The answer is using a MapFunction<V,K>, i.e. we define a new MapFunction that extracts a key from each item in our dataset

$$\mathsf{map} (v1) \to (k1)$$

 Datasets support the groupByKey method, that uses a MapFunction like the one above to perform the conversion

Dataset<V>.groupByKey(MapFunction<V,K>, Encoder<K>) → KeyValueGroupedDataset<K,V>

- KeyValueGroupedDatasets support the same types of operations that normal Datasets do, just based on groups
- Map groups acts as an aggregator for all items with the same key

```
mapGroups (k1,Iterator<v1>) → (v2)
```

MAP GROUPS

```
East or
                      Country
              West
                                 Revenue
                                (billions, USD)
 Dataset<CGR>
     new CGR("E","China",46)
     new CGR("W","US",40)
     new CGR("E","Japan",22)
     new CGR("E","S-Korea",8)
                                                       East or
     new CGR("W", "Germany", 6)
                                                       West
                       groupByKey(MapFunction<CGR,String>)
KeyValueGroupedDataset<String,CGR>
     <"E", CGR("E", "China", 46)>
     <"W", CGR("W","US",40)>
     <"E", CGR("E", "Japan", 22)>
```

<"E", CGR("E", "S-Korea", 8)> <"W", CGR("W", "Germany", 6)>

Sum Revenue

mapGroups(MapGroupsFunction<String,CGR,Integer>)

Dataset<Integer>

<76> <46>

FLATMAP GROUPS

 FlatMap groups works like map groups, but returns an iterator so that 0, 1 or many items can be returned

```
mapGroups (k1,Iterator<v1>) → (v2)
flatMapGroups (k1,Iterator<v1>) → Iterator<v2>
```

 Map functions convert KeyValueGroupedDatasets back to normal datasets by combining all items that share each key

REDUCE GROUPS

- The group-based equivalent of reduce simply applies reduce for each key, returning the reduced output for each key
 - Because of this, there is **no** special ReduceGroupsFunction, a ReduceFunction is sufficient to perform reduceGroups
 - The output of a reduceGroups operation is a Dataset<Tuple2<K,V>>
 - Tuple2 is simply a Java class for holding the key value pair

SUM Example

KeyValueGroupedDataset.reduceGroups(ReduceFunction<V>) → Dataset<Tuple2<K,V>>
